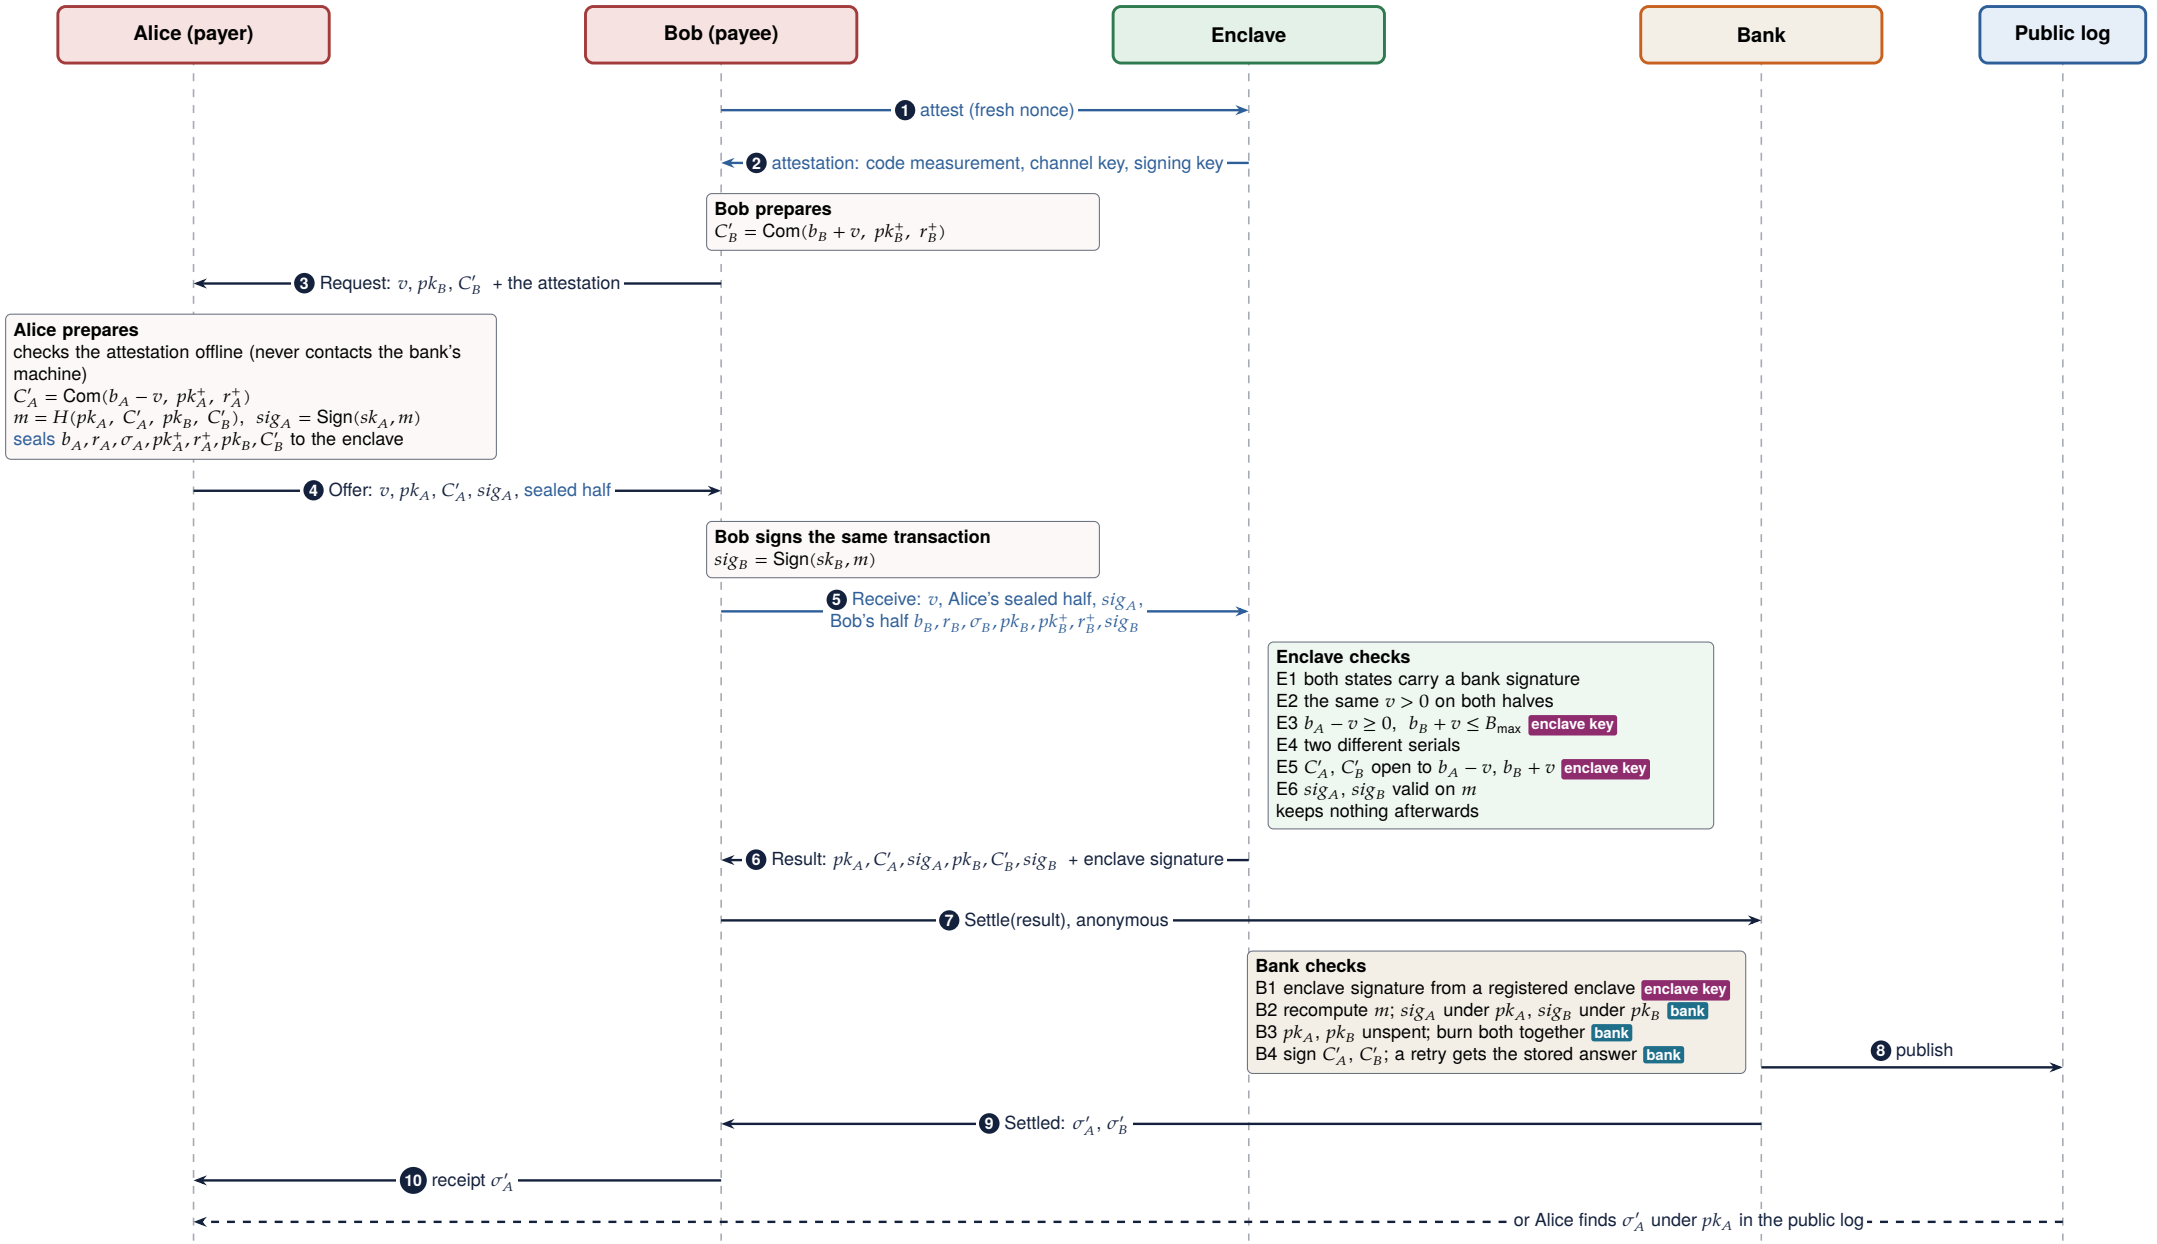
Round 1: a payment

Alice pays v to Bob. Bob makes the only enclave call and the only bank call, as in Platypus

blue sealed to the attested enclave bank check the bank does itself enclave key rests on the enclave's signing key
$^+$ next value, for example pk_A^+ is Alice's next serial key $\mathrm{Com}(b, pk, r)$ hides a state, σ is the bank's signature on it



Why both owners sign $m = H(pk_A, C'_A, pk_B, C'_B)$**.** Each serial is a one-time public key, so only the owner of a state can spend it, and the bank checks this itself (B2): signing keys never reach the enclave. The two signed commitments fix both new balances, so the amount and the payee cannot be changed. v is left out of m so the bank can recompute m without learning the amount. **What stays on the enclave's key:** balance conservation (E3, E5), which the bank cannot see.
